Summary

bw_timex is a Python package for time-explicit Life Cycle Assessment (LCA). Unlike conventional LCA, time-explicit LCA allows the quantification of environmental impacts of products and processes *over time*, considering their temporal distribution and evolution. As such, bw_timex enables simultaneously accounting for:

- the timing of processes throughout the supply chain (e.g., end-of-life treatment occurs 20 years after production),
- variable and/or evolving supply chains and technologies (e.g., increasing shares of renewable electricity or higher process efficiencies in the future), and
- the timing of emissions (enabling dynamic characterization).

To achieve this, bw_timex uses graph traversal to convolve process-relative temporal distributions through the supply chain. From the resulting timeline of technosphere exchanges, Life Cycle Inventories (LCIs) are automatically linked across time-specific background databases. The resulting time-explicit LCI reflects the current technology status within the product system at the actual time of each process. Moreover, bw_timex preserves the timing of emissions, enabling both dynamic and static Life Cycle Impact Assessment.

Statement of need

LCA traditionally assumes a static system, where all processes occur simultaneously and do not change over time (Heijungs & Suh, 2002). To add a temporal dimension to LCA, the fields of dynamic LCA (dLCA) and prospective LCA (pLCA) have emerged. While dLCA focuses on when processes and emissions occur and how impacts are distributed over time (*temporal distribution*), it typically assumes that the underlying product system remains the same (Beloin-Saint-Pierre et al., 2020). Conversely, while pLCA tracks how processes evolve (*temporal evolution*) using future scenarios, it generally only assesses a single (future) point in time, ignoring that processes occur at different times across a product's life cycle (Arvidsson et al., 2024).

bw_timex provides a framework for time-explicit LCA calculations within the Brightway ecosystem (Mutel, 2017). It combines considerations of temporal distribution and evolution by accounting for both the timing of processes and emissions as well as the state of the product system at the respective points in time. This makes bw_timex particularly useful for studies involving variable or strongly evolving product systems, long-lived products, biogenic carbon, and scenario analyses.

State of the field

Existing dLCA tools such as `Temporalis` (Cardellini et al., 2018) handle temporal distributions but not system evolution. Conversely, pLCA tools like `premise` (Sacchi et al., 2022), `Futura` (Joyce & Björklund, 2022), and `pathways` (Sacchi & Hahn-Menacho, 2024) model evolving systems but not temporal distributions within the supply chain. Two recent tools combine both temporal distribution and evolution: `ProsperDyn` (Lang-Quantzendorff & Beermann, 2025) and `TRAILS` (Sacchi, 2026). `ProsperDyn` is presently provided as a collection of research notebooks with limited documentation and without a consolidated, performance-oriented software architecture suitable for broader reuse. `TRAILS`, although methodologically advanced, currently relies on annual discretization and sequential year-specific calculations rather than a unified matrix-based integration of both dimensions.

`bw_timex` uniquely embeds the time dimension directly into the technosphere and biosphere matrices, enabling flexible temporal resolution within a single matrix-based framework. This allows efficient computation and seamless integration with the broader `Brightway` ecosystem.

Workflow

A time-explicit LCA with `bw_timex` follows four main steps, as illustrated in Figure 1. First, a conventional product system model is temporalized by adding process-relative temporal distributions (rTDs) to the exchanges (cf. Cardellini et al. (2018)). These rTDs describe how the amount of a technosphere or biosphere exchange is distributed over time, relative to the consuming or emitting process. In addition, temporal evolution of foreground processes can be defined through time-specific parameters. In Step 2, a timeline of technosphere exchanges is constructed by convolving rTDs along the supply chain, starting from the absolute reference time for the demand, which is defined by the user. In Step 3, the exchanges in the timeline are re-linked to time-specific background databases that reflect the technology landscape at specific points in time. Based on the temporally re-linked product system, a time-explicit LCI is calculated, preserving the timing of processes and emissions. The inventory is calculated following the conventional matrix-based LCA formulation (Heijungs & Suh, 2002), with the time dimension embedded in the matrices through additional row/column pairs. In Step 4, these emissions are characterized, either using standard characterization factors or by applying dynamic characterization functions that take the emissions' timing into account.
